

Operating Systems (INFR10079) 2023/2024 Semester 2

Threads (Basics)

abarbala@inf.ed.ac.uk

Chapter 4.1 (all), 4.2 (all)

Overview

- Concurrency vs Parallelism
- Process vs Thread
- Threads

What's "in" a process?

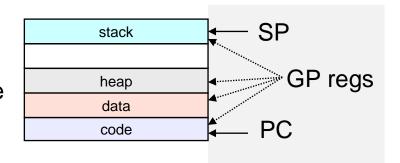

From previous slide-set

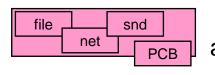

instruction

flow

- A process consists of (at least)
 - An address space, containing
 - Code (instructions) for the running program
 - Data for the running program (static data, heap data, stack)
 - A CPU state, consisting of
 - Program counter (PC), indicating the next instruction
 - Stack pointer, current stack position
 - Other general-purpose register values
 - A set of OS resources
 - Open files, network connections, sound channels, ...

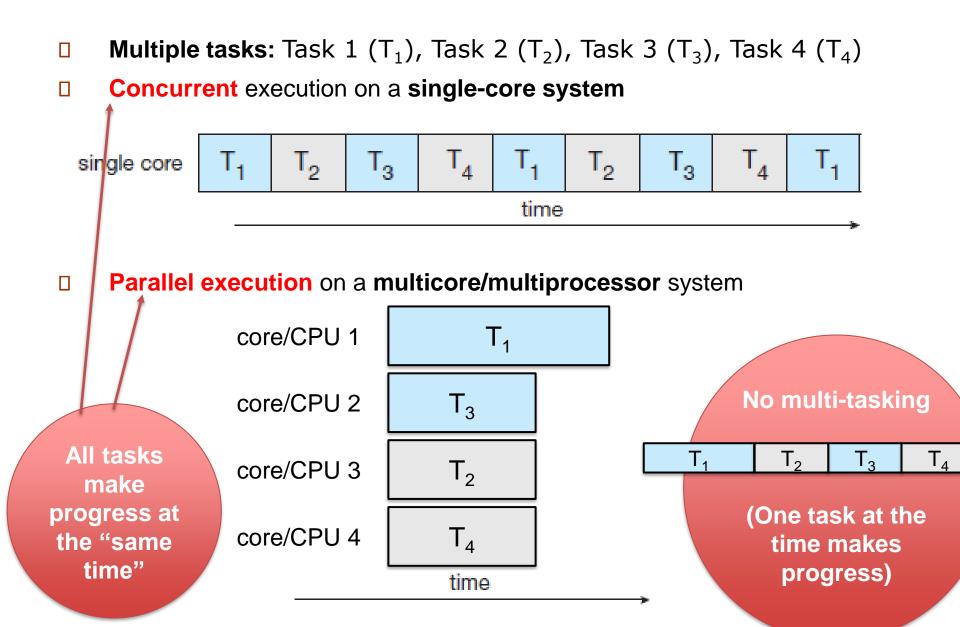

Process address space

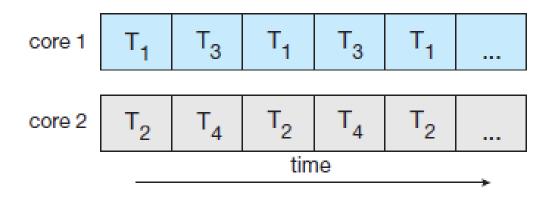

OS kernel address space

Concurrency vs Parallelism

Concurrency and Parallelism

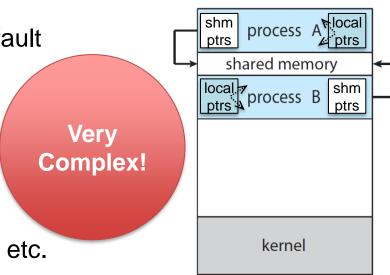

Both Concurrency and Parallelism

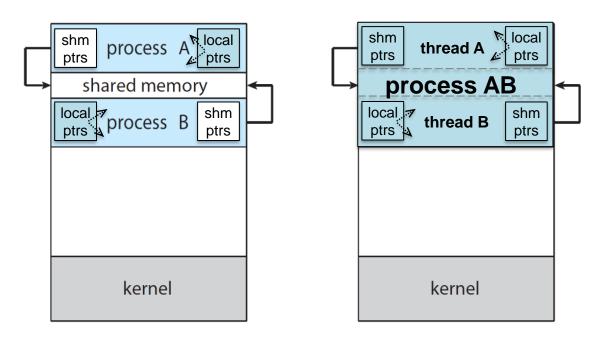

- Multiple processes to get concurrency and parallelism
 - Programs (code) of distinct processes are isolated from each other
- What if they need to communicate/share data?
 - Message passing, OS in the middle slow
 - What about Shared memory?

Concurrent/parallel Communicating Processes

- Given the process abstraction
 - 1. Fork several processes
 - 2. Cause each of them to *map* to the same memory to share data
 - See **shmget()** API for one way to do this
 - 3. Make them both to *open* the same OS resources
- Cumbersome
 - OS resources not shared by default
- <u>Limited shareability</u>
 - Not all pointers work
- Inefficient
 - Space: PCB, page tables, etc.
 - Time: creating OS structures, fork/copy address space, etc.

From Processes to Threads

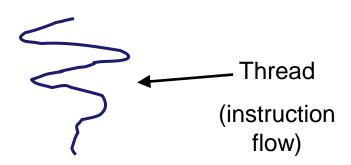

- Multiple processes to get concurrency and parallelism
 - Programs (code) of distinct processes are isolated from each other
- Multiple threads to get concurrency and parallelism
 - Threads "share a process" same address space, OS resources
 - Threads different instruction flows private stack, CPU state

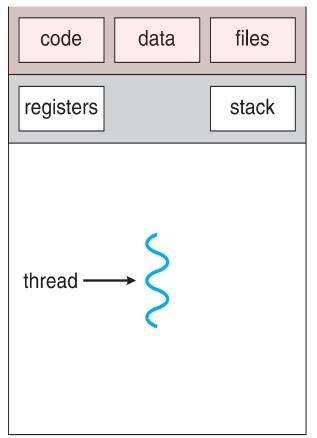

Threads

Key idea

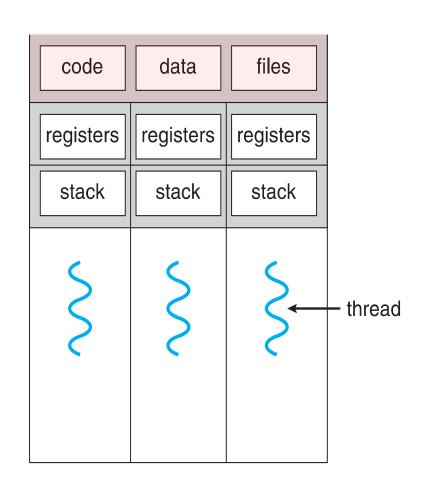

- Separate the foundational components of a process (address space, execution state, OS resources)
- Into different abstractions/entities
 - PROCESS: address space, OS resources
 - THREAD: CPU state (execution state)
 - program counter, stack pointer, other registers

Single-threaded and Multithreaded Processes

single-threaded process

multithreaded process

Use Case Scenario

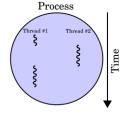

Various instruction flows

- run the same or different code
- access the same data (or part of it)
- have the same privileges
- use the same OS resources

Each instruction flow has hardware execution state

- Execution stack and stack pointer (SP)
 - Traces state of procedure calls made
- Program counter (PC)
 - Next instruction to be executed
- Set of general-purpose processor registers and their values

Threads and Processes

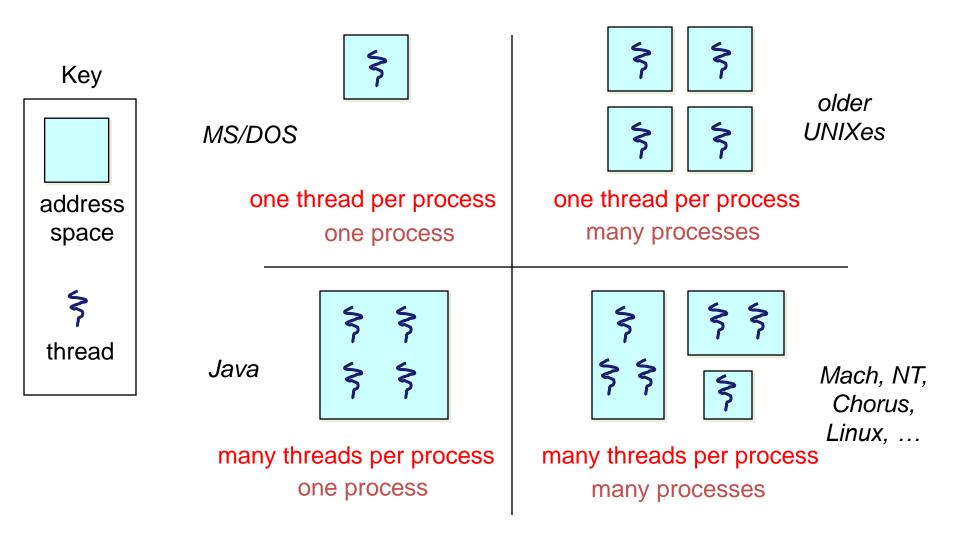

- Most modern OS's (Mach (Mac OS), Chorus, Windows, UNIX) support
 - Process: defines the address space and process' OS resources
 - Thread: defines a sequential execution flow within a process
- A thread is bound to a single process (thus address space)
 - However, processes (and address spaces) can have multiple threads executing within them
 - Sharing data between threads is cheap: all see the same address space
 - Creating threads is cheap too!
- Threads become the unit of scheduling
 - But depends on implementation (see next slides)
 - Processes are just containers in which threads execute

Communication

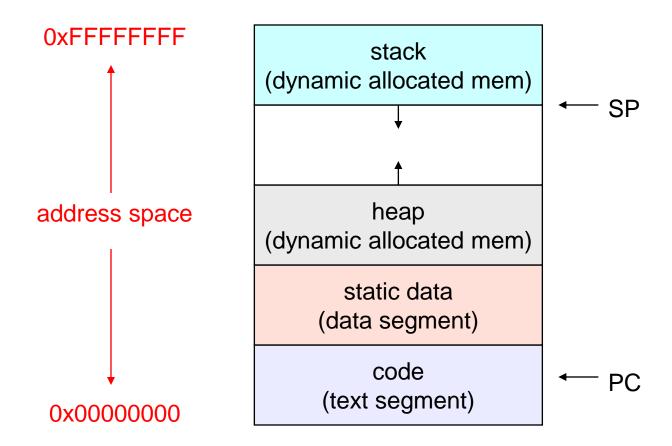

- Threads are diverse execution flows sharing an address space (and OS resources)
- Address spaces provide isolation
 - If you can't name it, you can't read nor write it
- Threads are in the same address space
 - Same name space (memory addresses)
 - Update a shared variable

Historical Design Space

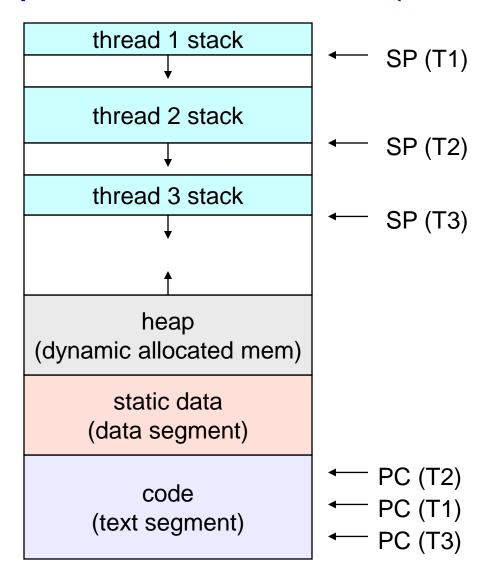

(Old) Process Address Space (32bit)

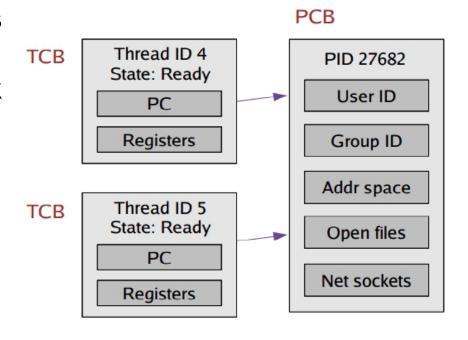

(New) Address Space with Threads (32bit)

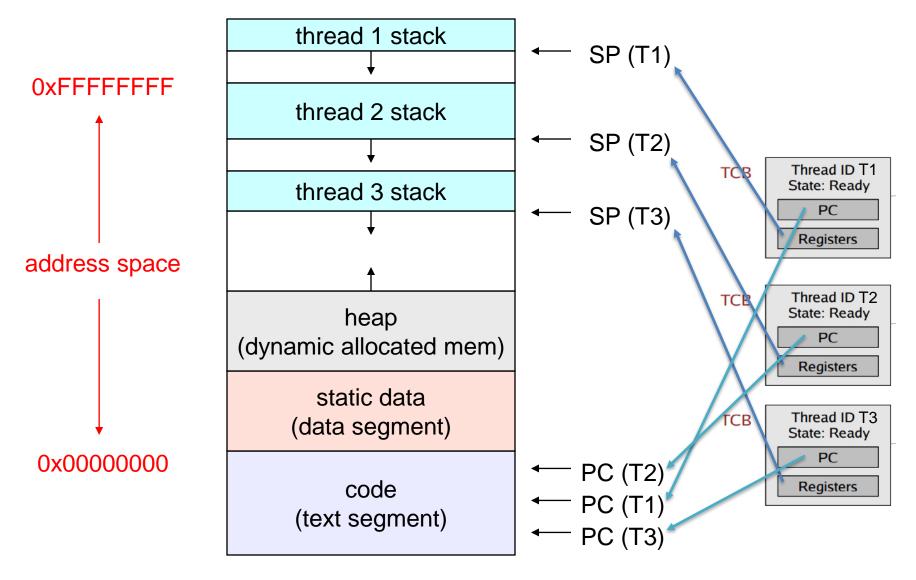

Thread Control Block (TCB) #1

- A PCB for each process
- Break the PCB into two pieces
- Info on program execution stored in Thread Control Block (TCB)
 - Program counter
 - CPU registers
 - Scheduling information
 - Pending I/O information
- Other infos stored in Process Control Block (PCB)
 - Memory management information
 - Accounting information

Thread Control Block (TCB) #2

Example Applications

- Multithreading is useful for
 - Handling concurrent events (e.g., web servers and clients)
 - Building parallel programs (e.g., matrix multiply, ray tracing)
 - Improving program structure (divide and conqueror)
- Multithreading is useful on a uniprocessor
 - Even though only one thread can run at a time

Terminology Note

- There is the potential for some confusion
 - "process" == "address space + OS resources + single execution flow"
 - OR
 - "process" == "address space + OS resources + multiple execution flows"
- Single-threaded process: 1 thread
- Multi-threaded process: N>1 threads
